

UNIT – 5 LAB EXERSICE

NAME : JASMITHA R

REG NO : 192524295

1. There are $3n$ piles of coins of varying size, you and your friends will take piles of coins as follows: In each step, you will choose any 3 piles of coins (not necessarily consecutive). Of your choice, Alice will pick the pile with the maximum number of coins. You will pick the next pile with the maximum number of coins. Your friend Bob will pick the last pile. Repeat until there are no more piles of coins. Given an array of integers piles where piles[i] is the number of coins in the ith pile. Return the maximum number of coins that you can have.

```
1 def maxCoins(piles):
2     piles.sort()
3     n = len(piles)
4     ans = 0
5     i = n - 2
6
7     for _ in range(n // 3):
8         ans += piles[i]
9         i -= 2
10
11     return ans
12
13 piles = [2,4,1,2,7,8]
14 print(maxCoins(piles))
```

If your code takes input, add it in the above box

Output

Status : Successfully executed

Time: 0.0100 secs Memory: 8.984 Mb

Your Output

9

2. You are given a 0-indexed integer array coins, representing the values of the coins available, and an integer target. An integer x is obtainable if there exists a subsequence of coins that sums to x. Return the minimum number of coins of any value that need to be added to the array so that every integer in the range [1, target] is obtainable. A subsequence of an array is a new non- empty array that is formed from the original array by deleting some (possibly none) of the elements without disturbing the relative positions of the remaining elements.

```

1- def minPatches(coins, target):
2-     coins.sort()
3-     reach = 1
4-     i = 0
5-     count = 0
6-
7-     while reach <= target:
8-         if i < len(coins) and coins[i] <= reach:
9-             reach += coins[i]
10-            i += 1
11-         else:
12-             reach += reach
13-             count += 1
14-
15-     return count
16-
17- coins = [1,4,10]
18- target = 19
19- print(minPatches(coins, target))

```

Output

Status : Successfully executed

Time: 0.0000 secs Memory: 8.884 Mb

Your Output

2

3. You are given an integer array jobs, where jobs[i] is the amount of time it takes to complete the ith job. There are k workers that you can assign jobs to. Each job should be assigned to exactly one worker. The working time of a worker is the sum of the time it takes to complete all jobs assigned to them. Your goal is to devise an optimal assignment such that the maximum working time of any worker is minimized. Return the minimum possible maximum working time of any assignment.

```

1- def minimumTime(jobs, k):
2-     jobs.sort(reverse=True)
3-     workers = [0] * k
4-
5-     def backtrack(i):
6-         if i == len(jobs):
7-             return True
8-
9-         for j in range(k):
10-            if workers[j] + jobs[i] <= limit:
11-                workers[j] += jobs[i]
12-
13-                if backtrack(i + 1):
14-                    return True
15-
16-                workers[j] -= jobs[i]
17-
18-            if workers[j] == 0:
19-                break
20-
21-         return False
22-
23-     low = max(jobs)
24-     high = sum(jobs)
25-
26-     while low < high:
27-         limit = (low + high) // 2
28-         if backtrack(0):
29-             high = limit
30-         else:
31-             low = limit + 1
32-
33-     return low
34-
35- jobs = [1,2,4,7,8]
36- k = 2
37- print(minimumTime(jobs, k))

```

4. We have n jobs, where every job is scheduled to be done from startTime[i] to endTime[i], obtaining a profit of profit[i]. You're given the startTime, endTime and profit arrays, return the maximum profit you can take such that there are no two jobs in the subset with overlapping time range. If you choose a job that ends at time X you will be able to start another job that starts at time X.

```

1 def maxProfit(start, end, profit):
2     jobs = sorted(zip(start, end, profit))
3     n = len(jobs)
4     dp = [0] * (n + 1)
5
6     for i in range(1, n + 1):
7         s, e, p = jobs[i - 1]
8
9         j = i - 1
10        while j > 0 and jobs[j - 1][1] > s:
11            j -= 1
12
13        dp[i] = max(dp[i - 1], p + dp[j])
14
15    return dp[n]
16
17 start = [1,2,3,3]
18 end = [3,4,5,6]
19 profit = [50,10,40,70]
20
21 print(maxProfit(start, end, profit))

```

Your Output

120

5. Given a graph represented by an adjacency matrix, implement Dijkstra's Algorithm to find the shortest path from a given source vertex to all other vertices in the graph. The graph is represented as an adjacency matrix where $graph[i][j]$ denote the weight of the edge from vertex i to vertex j . If there is no edge between vertices i and j , the value is Infinity (or a very large number).

```

1 def dijkstra(graph, source):
2     n = len(graph)
3     dist = [float('inf')] * n
4     visited = [False] * n
5     dist[source] = 0
6
7     for _ in range(n):
8         u = -1
9
10        for i in range(n):
11            if not visited[i] and (u == -1 or dist[i] < dist[u]):
12                u = i
13
14        visited[u] = True
15
16        for v in range(n):
17            if graph[u][v] != float('inf'):
18                dist[v] = min(dist[v], dist[u] + graph[u][v])
19
20    return dist
21
22 I = float('inf')
23
24 graph = [
25     [0,10,3,I,I],
26     [I,0,1,2,I],
27     [I,4,0,8,2],
28     [I,I,1,0,7],
29     [I,I,1,9,0]
30 ]
31
32 print(dijkstra(graph, 0))

```

Your Output

[0, 7, 3, 9, 5]

6. Given a graph represented by an edge list, implement Dijkstra's Algorithm to find the shortest path from a given source vertex to a target vertex. The graph is represented as a list of edges where each edge is a tuple (u, v, w) representing an edge from vertex u to vertex v with weight w .

```

1 import heapq
2
3 def dijkstra(n, edges, source, target):
4     graph = [[] for _ in range(n)]
5
6     for u, v, w in edges:
7         graph[u].append((v, w))
8
9     dist = [float('inf')] * n
10    dist[source] = 0
11    pq = [(0, source)]
12
13    while pq:
14        d, u = heapq.heappop(pq)
15
16        if u == target:
17            return d
18
19        if d > dist[u]:
20            continue
21
22        for v, w in graph[u]:
23            nd = d + w
24
25            if nd < dist[v]:
26                dist[v] = nd
27                heapq.heappush(pq, (nd, v))
28
29    return dist[target]
30
31 edges = [
32     (0,1,7),(0,2,9),(0,5,14),
33     (1,2,10),(1,3,15),(2,3,11),
34     (2,5,2),(3,4,6),(4,5,9)
35 ]
36
37 print(dijkstra(6, edges, 0, 4))

```

7. Given a set of characters and their corresponding frequencies, construct the Huffman Tree and generate the Huffman Codes for each character.

```

1 import heapq
2
3 def huffman(chars, freq):
4     heap = [[f, c, ""] for c, f in zip(chars, freq)]
5     heapq.heapify(heap)
6
7     while len(heap) > 1:
8         a = heapq.heappop(heap)
9         b = heapq.heappop(heap)
10
11         for x in a[1:]:
12             if isinstance(x, str):
13                 pass
14
15         heapq.heappush(heap, [a[0] + b[0], a, b])
16
17     codes = {}
18
19     def generate(node, code=""):
20         if isinstance(node[1], str):
21             codes[node[1]] = code
22         else:
23             generate(node[1], code + "0")
24             generate(node[2], code + "1")
25
26     generate(heap[0])
27     return codes
28
29 chars = ['a','b','c','d']
30 freq = [5,9,12,13]
31
32 print(huffman(chars, freq))

Your Output

{'a': '00', 'b': '01', 'c': '10', 'd': '11'}

8. Given a Huffman Tree and a Huffman encoded string, decode the string to get the original message.

```
1 def decode(codes, encoded):
2     result = ""
3     temp = ""
4
5     reverse = {v: k for k, v in codes.items()}
6
7     for bit in encoded:
8         temp += bit
9
10        if temp in reverse:
11            result += reverse[temp]
12            temp = ""
13
14    return result
15
16 codes = {
17     'a': '110',
18     'b': '10',
19     'c': '0',
20     'd': '111'
21 }
22
23 encoded = "1101100111110"
24
25 print(decode(codes, encoded))
```
